

Your agent does the work. Your Clone decides what comes next.

A QM extension that turns remembered context into the next instruction, review, and correction.

Press Tab once to accept the suggestion.

Press Tab twice to start the Clone mode.

Press Stop to take control back.

WHAT THE DEMO PROVES

The review changes the work

QM reported an unverified draft. Clone requested five known behaviors and a 50-word post. QM revised the brief against recorded facts.

Memory has visible evidence

Official GBrain retrieves scoped human-history records for predictions and reviews. Evidence can be opened from the interface.

Stop leaves the loop paused

The revised response and actual Stop are visible. Independent build verification and approval to publish are not established by this recording.

[Upstream QM PR](#)

The upstream PR is an open text proposal. The working implementation is in the fork.

One premise. One visible loop.

Approximate delivery targets. Pause at the handoff and let the correction speak.

30 SECONDS / 72 WORDS

Your agent does the work. You still decide what comes next.

Clone-in-the-Loop extends QM with your judgment. GBrain retrieves relevant Codex and Claude history and explicitly shared team feedback, so your Clone can suggest the next prompt.

Press Tab once to accept the suggestion. Press Tab twice to start the Clone mode.

QM executes. Your Clone reviews the result and sends one clear correction. They keep taking turns until you press Stop.

60 SECONDS / 158 WORDS

What if your past feedback could guide your agent's next step?

Clone-in-the-Loop is a QM fork for that workflow. GBrain retrieves relevant Codex and Claude sessions and explicitly shared team feedback to personalize the next prompt. Use it across Research, Product, and Marketing.

Press Tab once to accept the suggestion. Press Tab twice to start the Clone mode.

QM does the work. Your Clone reviews the result and asks for a specific correction. In the recorded launch example, QM reported an unverified draft. Clone asked it to use five known product behaviors and keep the post to exactly 50 words. QM revised the brief against the recorded facts. Stop paused the loop. The recording does not establish independent build verification or approval to publish.

Goals show the work. Inbox suggests what comes next. In the team workspace, choose Clone Garry for another perspective, with shared memory kept separate from personal history.

QM executes. Your Clone carries your judgment.

The details behind the claim.

What did you build on QM?

A source extension with next-prompt prediction, continuous execution and review, scoped memory, teammate selection, and a compact web UI. QM supplies the actual turns and execution lifecycle.

How does GBrain change the result?

Its official PGLite engine stores human-history records. Source-scoped keyword recall supplies evidence for the next instruction and the review. The user can inspect those excerpts. Hosted federation and vector search are outside this build.

What did you verify?

The filmed launch cycle shows QM revising against recorded facts and Stop pausing the loop. Earlier checks separately covered ten iterations, restart persistence, memory scope and a Product tool with three independently passing tests. See the verification record for boundaries.

Where does private context go?

Imported history is stored locally. Team retrieval excludes personal sources; selected excerpts go to the configured model provider. This is a trusted local prototype with one operator, not production multi-user isolation.

Is Clone Garry the real Garry?

Clone Garry is a fictional demo teammate with invented shared history. It demonstrates how a teammate's review preferences can guide the loop.

What is the upstream status?

The implementation is in the public QM fork. The open Upstream QM PR is a short text proposal under QM's contribution policy; it has not been merged or accepted.
