

Your agent does the work. Your Clone decides what comes next.

A QM extension that turns remembered context into the next instruction, review, and correction.

Tab once: accept the suggested prompt.

Tab again: enable Clone. Stop: take control back.

WHAT THE DEMO PROVES

The review changes the work

The Clone caught a repeated call to action and requested tighter wording and specific sources. QM corrected the 50-word post and review checklist.

Memory has visible evidence

Official GBrain retrieves scoped human-history records for predictions and reviews. Evidence can be opened from the interface.

The result and Stop can be checked

We inspected the generated template and separately read back a paused session with no active run. The template still marks publication blocked until verification and approval.

[Demo on Loom](#)

[Upstream QM PR](#)

The upstream PR is an open text proposal. The working implementation is in the fork.

One premise. One visible loop.

Approximate delivery targets. Pause at the handoff and let the correction speak.

30 SECONDS / 82 WORDS

Your agent does the work. You still have to decide what comes next.

Clone-in-the-Loop uses your past instructions and feedback to help make that decision. GBrain retrieves the context, your Clone suggests the next instruction, and QM carries it out. Your Clone then reviews the result and asks for a correction.

Press Tab to accept a suggestion, Tab again to let the loop continue, and Stop to take control back.

QM executes. GBrain remembers. Your Clone keeps your judgment in the loop.

60 SECONDS / 167 WORDS

What if your past feedback could guide your agent's next step?

Founders use agents across research, product, and marketing, but they still have to write the follow-up, catch the missing detail, and start the next round.

We built Clone-in-the-Loop for that person. GBrain retrieves your past instructions and feedback so your Clone can suggest what you would ask next. QM carries out the instruction, and your Clone reviews the result and asks for any changes.

Press Tab to accept a suggestion, Tab again to let the loop continue, and Stop to take control back.

In our launch-review workflow, the Clone caught a repeated call to action and asked QM to revise the post. We checked the saved result: 50 words, one call to action, and a publication checklist. Pressing Stop left the Goal paused.

Shared team feedback can guide the same loop. Clone Garry demonstrates that idea using fictional history, kept separate from personal records.

QM executes. GBrain remembers. Your Clone keeps your judgment in the loop.

The details behind the claim.

What did you build on QM?

A source extension with next-prompt prediction, continuous execution and review, scoped memory, teammate selection, and a compact web UI. QM supplies the actual turns and execution lifecycle.

How does GBrain change the result?

Its official PGLite engine stores human-history records. Source-scoped keyword recall supplies evidence for the next instruction and the review. The user can inspect those excerpts. Hosted federation and vector search are outside this build.

What did you verify?

Real reviews, corrections, and generated files; a paused state after Stop; restart persistence; and personal/team retrieval boundaries. A Product task produced a command-line tool whose three tests passed independently. See the linked verification record for exact boundaries.

Where does private context go?

Imported history is stored locally. Team retrieval excludes personal sources; selected excerpts go to the configured model provider. This is a trusted local prototype with one operator, not production multi-user isolation.

Is Clone Garry the real Garry?

Clone Garry is a fictional demo teammate with invented shared history. It demonstrates how a teammate's review preferences can guide the loop.

What is the upstream status?

The implementation is in the public QM fork. The open Upstream QM PR is a short text proposal under QM's contribution policy; it has not been merged or accepted.
